Project: Overall Safety of Vechicles
CUNY SPS: DATA606

Richie Rivera

May 13, 2024

Abstract

Since 2012, cars have been growing larger and heavier and this phenomenon has been reported more often. For example, The Economist among other publications have published articles that are showing that vehicles across North America and Europe are growing larger.

This is a worrying race to the bottom as larger vehicles are worse for the environment and are seemingly much less safe for society. Across the country, there are a growing number of local governments implementing vision 0 initiatives to reduce the number of vehicular related injuries and fatalities.

In this report, we will use statistical methods to verify if larger vehicles are indeed statistically significantly more likely to injure or kill someone in the event of a crash.

Data

We will be working with the "Motor Vehicle Collisions - Crashes" dataset provided by the City of New York. This dataset contains vehicular crashes in NYC which were reported by NYPD from July 2012 through the end of April 2024. Each observation in the dataset represents one crash.

This dataset contains 2,084,770 observations with 1,651 unique entries for vehicle class. For this analysis, we will be grouping each vehicle class into either "Passenger Vehicle", "SUV/Pickup Truck", or "Other". We will also observe the fields corresponding to the number of people killed and injured per crash.

Research Question

Is there a statistically significant difference in incidents between vehicles of different body types when a crash results in an incident?

For the purpose of this analysis, an incident is defined as a crash where at least one person is injured or killed as a result of a crash.

We will investigate this by looking at the sum of incidents (dependent variable) by vehicle class (independent variable).

Our null hypothesis is that there is no difference in incident rates across different vehicle classes and our alternative hypothesis is that there is a difference in incident rates across different vehicle classes.

Summary Statistics

```
##

```
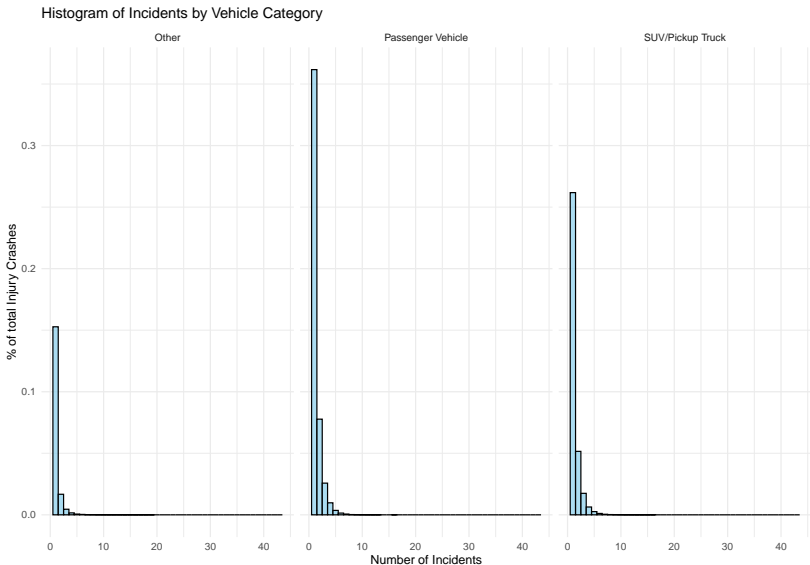

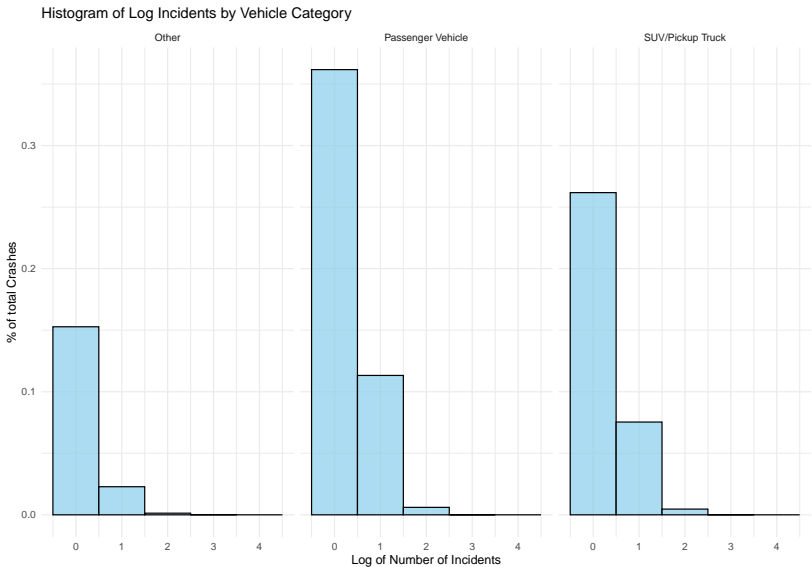

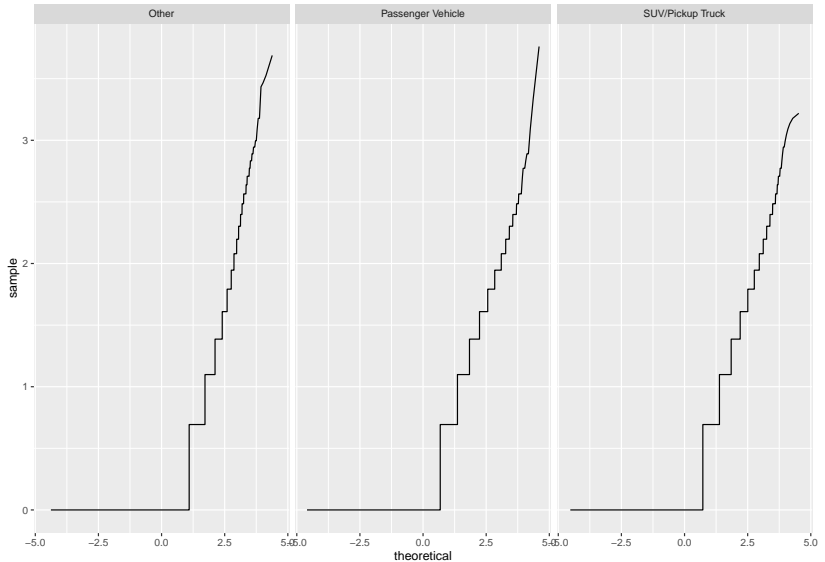

Histogram of Incidents

Histogram of Incidents by Vehicle Category

Histogram of Log Incidents

Histogram of Log Incidents by Vehicle Category

QQ Plot of Log Incidents

From here we can see that the distribution is somewhat normal.

Requirements for ANOVA

1. The Observations are independent within and across groups
2. The data within each group are nearly normal
3. The variability across the groups is about equal

We meet all of these requirements and can proceed with ANOVA.

ANOVA Results for log of Incidents

```
## # A tibble: 2 x 6
##   term               df  sumsq  meansq statistic p.value
##   <chr>            <dbl>  <dbl>   <dbl>     <dbl>   <dbl>
## 1 vehicle_category     2   646.   323.      2031.       0
## 2 Residuals       480351 76452.    0.159      NA      NA
```

From the summary above, the F-Value of 2031 indicates there is
evidence for a difference between the number of incidents and the
p.value of essentially 0 is evidence the result is statistically
significant.

Regression of the Results

```
##
## Call:
## lm(formula = log.TOTAL.PERSONS.INJURED.KILLED ~ vehicle_category,
##     data = log_hurt_crashes)
##
## Residuals:
##     Min      1Q  Median      3Q     Max
## -0.2209 -0.2209 -0.2106 -0.1213  3.5676
##
## Coefficients:

## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 0.3989 on 480351 degrees of freedom
## Multiple R-squared:  0.008384,   Adjusted R-squared:  0.00838
## F-statistic:  2031 on 2 and 480351 DF,  p-value: < 2.2e-16
```

From the regression results, we can see the coefficient for the
Passenger Vehicles category is the highest, followed by
SUV/Pickup Truck, and finally Other. Although we observe this
result, our Adjusted R-squared of 0.008 suggests only 0.8% of the
observed variance is due to the vehicle category. Interpreting our p
value of essentially 0, we also have evidence that this result is
statistically significant.

Conclusion

Recalling the means from before, we found that passenger vehicles had the greatest mean number of incidents. So these results provide evidence that crashes involving passenger vehicles are more likely to involve an incident (1.390 vs 1.377).

As reported by NHTSA, there were 42,939 people killed and 2,497,657 people injured in car crashes across the country in 2021. If we believe that every life is important, it's essential to realize how the choice of vehicles can affect people's lives

Total Monthly Crashes by Vehicle Category

Vehicle Category
- Other
- Passenger Vehicle
- SUV/Pickup Truck
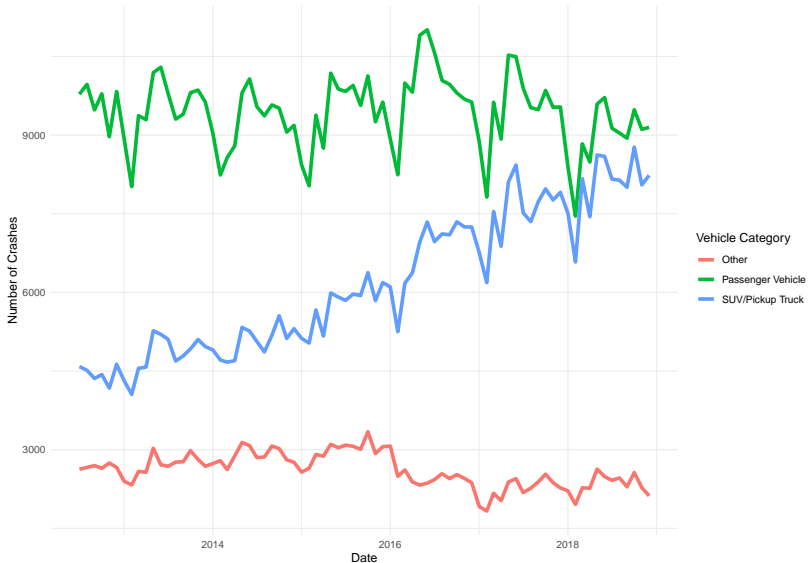

Limitations & Next Steps

This analysis was performed using data for crashes only looking at New York City. These results would likely vary across different levels of government and locations.

As a next step, it would be interesting to investigate the fatality rates across different vehicles. From the statistical summary, the fatality rate for SUV/Pickup Trucks is higher (0.006235 vs 0.004825). If the difference in mean fatality rates across vehicle types is statistically significant, then it can be evidence that SUV/Pickup Trucks are more fatal.
